With the rising popularity of flat or low budget gaming systems there is a need for a small and simple data recovery app. In this app I have included four different types of data recovery functionality. Note that in this experiment, we set $\mu_0=0.5$ since the skew parameter α is fixed at a given value, $\alpha=0.5$, and t_0 is given as the first sample of the τ value used in simulation. The signal-to-noise ratio (SNR) is set to 3 dB. In Fig. 1, we show the relationship between S_q and τ for $\alpha=0.5$. We can see that there exists a local maximum for S_q at $\tau \approx -0.015$. Also, we observe that the value of S_q increases as τ decreases, and that there exists a local maximum at $\tau \approx -0.025$. Finally, we confirm that the value of S_q in the case of $\tau=-0.025$ is closest to the empirical distribution, as shown in Fig. 2. This result shows that the value of S_q is a good indicator of the approximation accuracy and the bias, and that it can be used as a criterion for selecting the optimal value of τ . In addition, we see that the result of $\tau=-0.025$ in Fig. 2 is consistent with the result of $S_q=35$ in Fig. 3. Note that the bias in the case of $\tau=-0.025$ is much smaller than the bias in the case of $\tau=-0.015$.
